Array in Javascript : special variable that can hold more that 1 value.

→ fundamental data structure that store order collection of of data.

→ index start from zero, 0.

→ Syntax

```
let/var/const arrayName = [ ];
```

eg `const fruits = ["Apple", "Mango", "Orange"];`

`Console.log(arrayName[0]);`

- Length properties return total no. data

- Mutable v/s Immutable
  + Array are mutable object, two can change/modify the original value after creating it.

- To treate Array as immutable we should use such method that return new array instead of modifying original.

  eg [map, filter, slice]

* Array /vs object:

Array.isArray() : method that used for to check the passing argument is Array or not.

+ JS. array are object, optimed for ordered collections + it provide some built in method.

eg
- push()
- pop()
- shift()
- unshift()

} method.

Object don't have length, built in method

* Sparse Array: is Array that contain whole, or Empty slots this happed when index is skip or length is set to greater that no. of elements.

Sparse array is created by deleting element or
- By setting length properties > Larger value
(it give empty element)

* to delete element from array used delete keyword

```
let Num = [1,2,3];
delete Num[0]
```

1. array
2. indexing
3. mutably v/s immutably
4. Length properties
5. sparse Array
6. Array's object
